Group 1

↓

1

2

3

4

5

6

7

8

Hydrogen

1

H

explosive gas, lightest element; 90% of atoms in the universe, sun and stars, water (H<sub>2</sub>O), life's organic molecules

Alkali Metals

2

Be

very reactive and readily form compounds but are not found free in nature. They form salts and alkali (acid-neutralizing) compounds such as baking soda. In pure form, they are very soft metals which catch fire on contact with water.

Alkali Earth Metals

3

Mg

are reactive and readily form compounds but are not found free in nature. Their oxides are called alkali earths. In pure form, they are soft and somewhat brittle metals.

Transition Metals

4

Fe

are typical metals: they are strong, shiny, malleable (they can be hammered into shape), flexible (in thin sheets or wires), and they conduct both heat and electricity.

Chemical Bonding

5

Na

Atoms form molecules by bonding together. Atoms give, take, or share electrons to achieve full outer electron shells.

Groups

6

Li

Elements in the same group, or column, are similar because they typically have the same number of outer electrons. This table shows some easy-to-remember common numbers for each group.

Poor Metals

7

Pb

are usually soft and have low melting temperatures.

Metalloids

8

Si

are partly like metals and partly like nonmetals. For example, they are semiconductors, which means they conduct electricity in some conditions.

Nonmetals

9

C

in their solid state, are usually brittle (they break rather than bend) and they are insulators of both heat and electricity.

Halogens

10

F

are reactive nonmetals and readily form compounds but are not found free in nature. They combine with alkali metals to form salts (halogen means salt-former).

Noble Gases

11

Ne

are inactive, or inert. Each atom has exactly the number of electrons it needs to have a full outer shell, so these atoms almost never bond with other atoms. That is why these are all gases.

Atoms

12

H

An atom has a nucleus, made of protons and neutrons, surrounded by electrons orbiting in cloud-like shells. Smaller shells are surrounded by larger shells. The atomic number is the number of protons in an atom. This determines the chemical properties of the atom. Protons have positive electric charge, neutrons are neutral, and electrons are negative. Normally, an atom has equal numbers of protons and electrons. An ion is a charged atom with more or fewer electrons than protons. The atomic weight of an element is the average number of protons plus neutrons. You can easily estimate the atomic weight: it is usually 2 to 2.5 times the atomic number. An element is a substance made from one or more atoms of the same atomic number. A compound is a substance made from two or more elements chemically bonded.

Chemical Bonding

13

NaCl

Atoms form molecules by bonding together. Atoms give, take, or share electrons to achieve full outer electron shells.

Groups

14

Li

Elements in the same group, or column, are similar because they typically have the same number of outer electrons. This table shows some easy-to-remember common numbers for each group.

Poor Metals

15

Pb

are usually soft and have low melting temperatures.

Metalloids

16

Si

are partly like metals and partly like nonmetals. For example, they are semiconductors, which means they conduct electricity in some conditions.

Nonmetals

17

C

in their solid state, are usually brittle (they break rather than bend) and they are insulators of both heat and electricity.

Halogens

18

F

are reactive nonmetals and readily form compounds but are not found free in nature. They combine with alkali metals to form salts (halogen means salt-former).

Noble Gases

19

Ne

are inactive, or inert. Each atom has exactly the number of electrons it needs to have a full outer shell, so these atoms almost never bond with other atoms. That is why these are all gases.

Atoms

20

H

An atom has a nucleus, made of protons and neutrons, surrounded by electrons orbiting in cloud-like shells. Smaller shells are surrounded by larger shells. The atomic number is the number of protons in an atom. This determines the chemical properties of the atom. Protons have positive electric charge, neutrons are neutral, and electrons are negative. Normally, an atom has equal numbers of protons and electrons. An ion is a charged atom with more or fewer electrons than protons. The atomic weight of an element is the average number of protons plus neutrons. You can easily estimate the atomic weight: it is usually 2 to 2.5 times the atomic number. An element is a substance made from one or more atoms of the same atomic number. A compound is a substance made from two or more elements chemically bonded.

Chemical Bonding

21

NaCl

Atoms form molecules by bonding together. Atoms give, take, or share electrons to achieve full outer electron shells.

Groups

22

Li

Elements in the same group, or column, are similar because they typically have the same number of outer electrons. This table shows some easy-to-remember common numbers for each group.

Poor Metals

23

Pb

are usually soft and have low melting temperatures.

Metalloids

24

Si

are partly like metals and partly like nonmetals. For example, they are semiconductors, which means they conduct electricity in some conditions.

Nonmetals

25

C

in their solid state, are usually brittle (they break rather than bend) and they are insulators of both heat and electricity.

Halogens

26

F

are reactive nonmetals and readily form compounds but are not found free in nature. They combine with alkali metals to form salts (halogen means salt-former).

Noble Gases

27

Ne

are inactive, or inert. Each atom has exactly the number of electrons it needs to have a full outer shell, so these atoms almost never bond with other atoms. That is why these are all gases.

Atoms

28

H

An atom has a nucleus, made of protons and neutrons, surrounded by electrons orbiting in cloud-like shells. Smaller shells are surrounded by larger shells. The atomic number is the number of protons in an atom. This determines the chemical properties of the atom. Protons have positive electric charge, neutrons are neutral, and electrons are negative. Normally, an atom has equal numbers of protons and electrons. An ion is a charged atom with more or fewer electrons than protons. The atomic weight of an element is the average number of protons plus neutrons. You can easily estimate the atomic weight: it is usually 2 to 2.5 times the atomic number. An element is a substance made from one or more atoms of the same atomic number. A compound is a substance made from two or more elements chemically bonded.

Chemical Bonding

29

NaCl

Atoms form molecules by bonding together. Atoms give, take, or share electrons to achieve full outer electron shells.

Groups

30

Li

Elements in the same group, or column, are similar because they typically have the same number of outer electrons. This table shows some easy-to-remember common numbers for each group.

Poor Metals

31

Pb

are usually soft and have low melting temperatures.

Metalloids

32

Si

are partly like metals and partly like nonmetals. For example, they are semiconductors, which means they conduct electricity in some conditions.

Nonmetals

33

C

in their solid state, are usually brittle (they break rather than bend) and they are insulators of both heat and electricity.

Halogens

34

F

are reactive nonmetals and readily form compounds but are not found free in nature. They combine with alkali metals to form salts (halogen means salt-former).

Noble Gases

35

Ne

are inactive, or inert. Each atom has exactly the number of electrons it needs to have a full outer shell, so these atoms almost never bond with other atoms. That is why these are all gases.

Atoms

36

H

An atom has a nucleus, made of protons and neutrons, surrounded by electrons orbiting in cloud-like shells. Smaller shells are surrounded by larger shells. The atomic number is the number of protons in an atom. This determines the chemical properties of the atom. Protons have positive electric charge, neutrons are neutral, and electrons are negative. Normally, an atom has equal numbers of protons and electrons. An ion is a charged atom with more or fewer electrons than protons. The atomic weight of an element is the average number of protons plus neutrons. You can easily estimate the atomic weight: it is usually 2 to 2.5 times the atomic number. An element is a substance made from one or more atoms of the same atomic number. A compound is a substance made from two or more elements chemically bonded.

Chemical Bonding

37

NaCl

Atoms form molecules by bonding together. Atoms give, take, or share electrons to achieve full outer electron shells.

Groups

38

Li

Elements in the same group, or column, are similar because they typically have the same number of outer electrons. This table shows some easy-to-remember common numbers for each group.

Poor Metals

39

Pb

are usually soft and have low melting temperatures.

Metalloids

40

Si

are partly like metals and partly like nonmetals. For example, they are semiconductors, which means they conduct electricity in some conditions.

Nonmetals

41

C

in their solid state, are usually brittle (they break rather than bend) and they are insulators of both heat and electricity.

Halogens

42

F

are reactive nonmetals and readily form compounds but are not found free in nature. They combine with alkali metals to form salts (halogen means salt-former).

Noble Gases

43

Ne

are inactive, or inert. Each atom has exactly the number of electrons it needs to have a full outer shell, so these atoms almost never bond with other atoms. That is why these are all gases.

Atoms

44

H

An atom has a nucleus, made of protons and neutrons, surrounded by electrons orbiting in cloud-like shells. Smaller shells are surrounded by larger shells. The atomic number is the number of protons in an atom. This determines the chemical properties of the atom. Protons have positive electric charge, neutrons are neutral, and electrons are negative. Normally, an atom has equal numbers of protons and electrons. An ion is a charged atom with more or fewer electrons than protons. The atomic weight of an element is the average number of protons plus neutrons. You can easily estimate the atomic weight: it is usually 2 to 2.5 times the atomic number. An element is a substance made from one or more atoms of the same atomic number. A compound is a substance made from two or more elements chemically bonded.

Chemical Bonding

45

NaCl

Atoms form molecules by bonding together. Atoms give, take, or share electrons to achieve full outer electron shells.

Groups

46

Li

Elements in the same group, or column, are similar because they typically have the same number of outer electrons. This table shows some easy-to-remember common numbers for each group.

Poor Metals

47

Pb

are usually soft and have low melting temperatures.

Metalloids

48

Si

are partly like metals and partly like nonmetals. For example, they are semiconductors, which means they conduct electricity in some conditions.

Nonmetals

49

C

in their solid state, are usually brittle (they break rather than bend) and they are insulators of both heat and electricity.

Halogens

50

F

are reactive nonmetals and readily form compounds but are not found free in nature. They combine with alkali metals to form salts (halogen means salt-former).

Noble Gases

51

Ne

are inactive, or inert. Each atom has exactly the number of electrons it needs to have a full outer shell, so these atoms almost never bond with other atoms. That is why these are all gases.

Atoms

52

H

An atom has a nucleus, made of protons and neutrons, surrounded by electrons orbiting in cloud-like shells. Smaller shells are surrounded by larger shells. The atomic number is the number of protons in an atom. This determines the chemical properties of the atom. Protons have positive electric charge, neutrons are neutral, and electrons are negative. Normally, an atom has equal numbers of protons and electrons. An ion is a charged atom with more or fewer electrons than protons. The atomic weight of an element is the average number of protons plus neutrons. You can easily estimate the atomic weight: it is usually 2 to 2.5 times the atomic number. An element is a substance made from one or more atoms of the same atomic number. A compound is a substance made from two or more elements chemically bonded.

Chemical Bonding

53

NaCl

Atoms form molecules by bonding together. Atoms give, take, or share electrons to achieve full outer electron shells.

Groups

54

Li

Elements in the same group, or column, are similar because they typically have the same number of outer electrons. This table shows some easy-to-remember common numbers for each group.

Poor Metals

55

Pb

are usually soft and have low melting temperatures.

Metalloids

56

Si

are partly like metals and partly like nonmetals. For example, they are semiconductors, which means they conduct electricity in some conditions.

Nonmetals

57

C

in their solid state, are usually brittle (they break rather than bend) and they are insulators of both heat and electricity.

Halogens

58

F

are reactive nonmetals and readily form compounds but are not found free in nature. They combine with alkali metals to form salts (halogen means salt-former).

Noble Gases

59

Ne

are inactive, or inert. Each atom has exactly the number of electrons it needs to have a full outer shell, so these atoms almost never bond with other atoms. That is why these are all gases.

Atoms

60

H

An atom has a nucleus, made of protons and neutrons, surrounded by electrons orbiting in cloud-like shells. Smaller shells are surrounded by larger shells. The atomic number is the number of protons in an atom. This determines the chemical properties of the atom. Protons have positive electric charge, neutrons are neutral, and electrons are negative. Normally, an atom has equal numbers of protons and electrons. An ion is a charged atom with more or fewer electrons than protons. The atomic weight of an element is the average number of protons plus neutrons. You can easily estimate the atomic weight: it is usually 2 to 2.5 times the atomic number. An element is a substance made from one or more atoms of the same atomic number. A compound is a substance made from two or more elements chemically bonded.

Chemical Bonding

61

NaCl

Atoms form molecules by bonding together. Atoms give, take, or share electrons to achieve full outer electron shells.

Groups

62

Li

Elements in the same group, or column, are similar because they typically have the same number of outer electrons. This table shows some easy-to-remember common numbers for each group.

Poor Metals

63

Pb

are usually soft and have low melting temperatures.

Metalloids

64

Si

are partly like metals and partly like nonmetals. For example, they are semiconductors, which means they conduct electricity in some conditions.

Nonmetals

65

C

in their solid state, are usually brittle (they break rather than bend) and they are insulators of both heat and electricity.

Halogens

66

F

are reactive nonmetals and readily form compounds but are not found free in nature. They combine with alkali metals to form salts (halogen means salt-former).

Noble Gases

67

Ne

are inactive, or inert. Each atom has exactly the number of electrons it needs to have a full outer shell, so these atoms almost never bond with other atoms. That is why these are all gases.

Atoms

68

H

An atom has a nucleus, made of protons and neutrons, surrounded by electrons orbiting in cloud-like shells. Smaller shells are surrounded by larger shells. The atomic number is the number of protons in an atom. This determines the chemical properties of the atom. Protons have positive electric charge, neutrons are neutral, and electrons are negative. Normally, an atom has equal numbers of protons and electrons. An ion is a charged atom with more or fewer electrons than protons. The atomic weight of an element is the average number of protons plus neutrons. You can easily estimate the atomic weight: it is usually 2 to 2.5 times the atomic number. An element is a substance made from one or more atoms of the same atomic number. A compound is a substance made from two or more elements chemically bonded.

Chemical Bonding

69

NaCl

Atoms form molecules by bonding together. Atoms give, take, or share electrons to achieve full outer electron shells.

Groups

70

Li

Elements in the same group, or column, are similar because they typically have the same number of outer electrons. This table shows some easy-to-remember common numbers for each group.

Poor Metals

71

Pb

are usually soft and have low melting temperatures.

Metalloids

72

Si

are partly like metals and partly like nonmetals. For example, they are semiconductors, which means they conduct electricity in some conditions.

Nonmetals

73

C

in their solid state, are usually brittle (they break rather than bend) and they are insulators of both heat and electricity.

Halogens

74

F

are reactive nonmetals and readily form compounds but are not found free in nature. They combine with alkali metals to form salts (halogen means salt-former).

Noble Gases

75

Ne

are inactive, or inert. Each atom has exactly the number of electrons it needs to have a full outer shell, so these atoms almost never bond with other atoms. That is why these are all gases.

Atoms

76

H

An atom has a nucleus, made of protons and neutrons, surrounded by electrons orbiting in cloud-like shells. Smaller shells are surrounded by larger shells. The atomic number is the number of protons in an atom. This determines the chemical properties of the atom. Protons have positive electric charge, neutrons are neutral, and electrons are negative. The atomic weight of an element is the average number of protons plus neutrons. You can easily estimate the atomic weight: it is usually 2 to 2.5 times the atomic number. An element is a substance made from one or more atoms of the same atomic number. A compound is a substance made from two or more elements chemically bonded.

Chemical Bonding

77

NaCl

Atoms form molecules by bonding together. Atoms give, take, or share electrons to achieve full outer electron shells.

Groups

78

Li

Elements in the same group, or column, are similar because they typically have the same number of outer electrons. This table shows some easy-to-remember common numbers for each group.

Poor Metals

79

Pb

are usually soft and have low melting temperatures.

Metalloids

80

Si

are partly like metals and partly like nonmetals. For example, they are semiconductors, which means they conduct electricity in some conditions.

Nonmetals

81

C

in their solid state, are usually brittle (they break rather than bend) and they are insulators of both heat and electricity.

Halogens

82

F

are reactive nonmetals and readily form compounds but are not found free in nature. They combine with alkali metals to form salts (halogen means salt-former).

Noble Gases

83

Ne

are inactive, or inert. Each atom has exactly the number of electrons it needs to have a full outer shell, so these atoms almost never bond with other atoms. That is why these are all gases.

Atoms

84

H

An atom has a nucleus, made of protons and neutrons, surrounded by electrons orbiting in cloud-like shells. Smaller shells are surrounded by larger shells. The atomic number is the number of protons in an atom. This determines the chemical properties of the atom. Protons have positive electric charge, neutrons are neutral, and electrons are negative. Normally, an atom has equal numbers of protons and electrons. An ion is a charged atom with more or fewer electrons than protons. The atomic weight of an element is the average number of protons plus neutrons. You can easily estimate the atomic weight: it is usually 2 to 2.5 times the atomic number. An element is a substance made from one or more atoms of the same atomic number. A compound is a substance made from two or more elements chemically bonded.

Chemical Bonding

85

NaCl

Atoms form molecules by bonding together. Atoms give, take, or share electrons to achieve full outer electron shells.

Groups

86

Li

Elements in the same group, or column, are similar because they typically have the same number of outer electrons. This table shows some easy-to-remember common numbers for each group.

Poor Metals

87

Pb

are usually soft and have low melting temperatures.

Metalloids

88

Si

are partly like metals and partly like nonmetals. For example, they are semiconductors, which means they conduct electricity in some conditions.

Nonmetals

89

C

in their solid state, are usually brittle (they break rather than bend) and they are insulators of both heat and electricity.

Halogens

90

F

are reactive nonmetals and readily form compounds but are not found free in nature. They combine with alkali metals to form salts (halogen means salt-former).

Noble Gases

91

Ne

are inactive, or inert. Each atom has exactly the number of electrons it needs to have a full outer shell, so these atoms almost never bond with other atoms. That is why these are all gases.

Atoms

92

H

An atom has a nucleus, made of protons and neutrons, surrounded by electrons orbiting in cloud-like shells. Smaller shells are surrounded by larger shells. The atomic number is the number of protons in an atom. This determines the chemical properties of the atom. Protons have positive electric charge, neutrons are neutral, and electrons are negative. Normally, an atom has equal numbers of protons and electrons. An ion is a charged atom with more or fewer electrons than protons. The atomic weight of an element is the average number of protons plus neutrons. You can easily estimate the atomic weight: it is usually 2 to 2.5 times the atomic number. An element is a substance made from one or more atoms of the same atomic number. A compound is a substance made from two or more elements chemically bonded.

Chemical Bonding

93

NaCl

Atoms form molecules by bonding together. Atoms give, take, or share electrons to achieve full outer electron shells.

Groups

94

Li

Elements in the same group, or column, are similar because they typically have the same number of outer electrons. This table shows some easy-to-remember common numbers for each group.

Poor Metals

95

Pb

are usually soft and have low melting temperatures.

Metalloids

96

Si

are partly like metals and partly like nonmetals. For example, they are semiconductors, which means they conduct electricity in some conditions.

Nonmetals

97

C

in their solid state, are usually brittle (they break rather than bend) and they are insulators of both heat and electricity.

Halogens

98

F

are reactive nonmetals and readily form compounds but are not found free in nature. They combine with alkali metals to form salts (halogen means salt-former).

Noble Gases

99

Ne

are inactive, or inert. Each atom has exactly the number of electrons it needs to have a full outer shell, so these atoms almost never bond with other atoms. That is why these are all gases.

Atoms

100

H

An atom has a nucleus, made of protons and neutrons, surrounded by electrons orbiting in cloud-like shells. Smaller shells are surrounded by larger shells. The atomic number is the number of protons in an atom. This determines the chemical properties of the atom. Protons have positive electric charge, neutrons are neutral, and electrons are negative. Normally, an atom has equal numbers of protons and electrons. An ion is a charged atom with more or fewer electrons than protons. The atomic weight of an element is the average number of protons plus neutrons. You can easily estimate the atomic weight: it is usually 2 to 2.5 times the atomic number. An element is a substance made from one or more atoms of the same atomic number. A compound is a substance made from two or more elements chemically bonded.

Chemical Bonding

101

NaCl

Atoms form molecules by bonding together. Atoms give, take, or share electrons to achieve full outer electron shells.

Groups

102

Li

Elements in the same group, or column, are similar because they typically have the same number of outer electrons. This table shows some easy-to-remember common numbers for each group.

Poor Metals

103

Pb

are usually soft and have low melting temperatures.

Metalloids

104

Si

are partly like metals and partly like nonmetals. For example, they are semiconductors, which means they conduct electricity in some conditions.

Nonmetals

105

C

in their solid state, are usually brittle (they break rather than bend) and they are insulators of both heat and electricity.

Halogens

106

F

are reactive nonmetals and readily form compounds but are not found free in nature. They combine with alkali metals to form salts (halogen means salt-former).

Noble Gases

107

Ne

are inactive, or inert. Each atom has exactly the number of electrons it needs to have a full outer shell, so these atoms almost never bond with other atoms. That is why these are all gases.

Atoms

108

H

An atom has a nucleus, made of protons and neutrons, surrounded by electrons orbiting in cloud-like shells. Smaller shells are surrounded by larger shells. The atomic number is the number of protons in an atom. This determines the chemical properties of the atom. Protons have positive electric charge, neutrons are neutral, and electrons are negative. Normally, an atom has equal numbers of protons and electrons. An ion is a charged atom with more or fewer electrons than protons. The atomic weight of an element is the average number of protons plus neutrons. You can easily estimate the atomic weight: it is usually 2 to 2.5 times the atomic number. An element is a substance made from one or more atoms of the same atomic number. A compound is a substance made from two or more elements chemically bonded.

Chemical Bonding

109

NaCl

Atoms form molecules by bonding together. Atoms give, take, or share electrons to achieve full outer electron shells.

Groups

110

122

F

are reactive nonmetals and readily form compounds but are not found free in nature. They combine with alkali metals to form salts (halogen means salt-former).

Noble Gases

123

Ne

are inactive, or inert. Each atom has exactly the number of electrons it needs to have a full outer shell, so these atoms almost never bond with other atoms. That is why these are all gases.

Atoms

124

H

An atom has a nucleus, made of protons and neutrons, surrounded by electrons orbiting in cloud-like shells. Smaller shells are surrounded by larger shells. The atomic number is the number of protons in an atom. This determines the chemical properties of the atom. Protons have positive electric charge, neutrons are neutral, and electrons are negative. Normally, an atom has equal numbers of protons and electrons. An ion is a charged atom with more or fewer electrons than protons. The atomic weight of an element is the average number of protons plus neutrons. You can easily estimate the atomic weight: it is usually 2 to 2.5 times the atomic number. An element is a substance made from one or more atoms of the same atomic number. A compound is a substance made from two or more elements chemically bonded.

Chemical Bonding

125

NaCl

Atoms form molecules by bonding together. Atoms give, take, or share electrons to achieve full outer electron shells.

Groups

126

Li

Elements in the same group, or column, are similar because they typically have the same number of outer electrons. This table shows some easy-to-remember common numbers for each group.

Poor Metals

127

Pb

are usually soft and have low melting temperatures.

Metalloids

128

Si

are partly like metals and partly like nonmetals. For example, they are semiconductors, which means they conduct electricity in some conditions.

Nonmetals

129

C

in their solid state, are usually brittle (they break rather than bend) and they are insulators of both heat and electricity.

Halogens

130

F

are reactive nonmetals and readily form compounds but are not found free in nature. They combine with alkali metals to form salts (halogen means salt-former).

Noble Gases

131

Ne

are inactive, or inert. Each atom has exactly the number of electrons it needs to have a full outer shell, so these atoms almost never bond with other atoms. That is why these are all gases.

Atoms

132

H

An atom has a nucleus, made of protons and neutrons, surrounded by electrons orbiting in cloud-like shells. Smaller shells are surrounded by larger shells. The atomic number is the number of protons in an atom. This determines the chemical properties of the atom. Protons have positive electric charge, neutrons are neutral, and electrons are negative. Normally, an atom has equal numbers of protons and electrons. An ion is a charged atom with more or fewer electrons than protons. The atomic weight of an element is the average number of protons plus neutrons. You can easily estimate the atomic weight: it is usually 2 to 2.5 times the atomic number. An element is a substance made from one or more atoms of the same atomic number. A compound is a substance made from two or more elements chemically bonded.

Chemical Bonding
